Supervisors:  
Professor D. M. Paterson & Dr W. E. N. Austin  
University of St Andrews

In collaboration with Dr J. A. Godbold & Dr M. Solan  
University of Southampton

Funding for this project is provided by NERC and the University of St Andrews

## Talk Outline:

- Introduction: Foraminifera and Ocean Acidification
- Details on Experimental System
- Sampling Regime and Foraminiferal Picking Methods
- Preliminary Results
- Future Work

## 1. Foraminifera & Ocean Acidification:

Changes in seawater chemistry due to ocean acidification will have severe implications on marine organisms that construct carbonate shells and structures, including foraminifera.

Foraminifera are unicellular organisms that construct a shell (test) which, when the animal dies can remain in the sediment as a fossil

Shells (tests) hold the potential to record information on changing ocean chemistry, often leaving a microfossil record that permits reconstruction of environmental history

## 2. Foraminifera:

- Constitute one the most diverse groups of shelled microorganisms in modern oceans
- The type of shell material can determine where various species or their remains can survive
- Varying wall compositions = different sensitivities to dissolution

**Calcareous** forms secrete a  $\text{CaCO}_3$  test

**Hyaline**

**Porcellaneous**

**Agglutinated** forms build tests by cementing detrital material

### 3. Experimental System:

- Samples taken from long-term exposure experiments at Oceanlab, Aberdeen (now at University of Southampton)
- Mud sampled from Ythan Estuary, NE Scotland (Dec 2010)
- CO<sub>2</sub> treatments maintained by bubbling from a air-CO<sub>2</sub> mixing system
- Sub-samples from sediment cores to investigate the foraminiferal response over time

#### 4. Sampling Regime:

- Samples taken at 12 time points (January 2011 – March 2012)

- CO<sub>2</sub> Treatments: 380, 750 and 1000 ppm
- Temperature: 10°C and Ambient
- Four replicates for each (combination of surface scrapes from three points within core)
- Same area never sampled twice

## 5. Sample Processing & Foraminiferal Picking Methods:

- Samples fixed and stained with Rose Bengal at time of sampling
- Sediment sieved ( $>63\ \mu\text{m}$ ), washed & dried ( $< 40\ ^\circ\text{C}$ )
- Dry weights determined & samples stored
- Foraminifera extracted using standard micropalaeontological techniques

## 6. Predicted trends under environmental stress:

**LOW STRESS**

**HIGH STRESS**

### Data collection on:

- Species dominance
- Species diversity
- Species presence/absence
- Species abundances
- Biometry

Redrawn from Murray (2000)

## 7. Preliminary Observations (1):

- 44 species identified from total (live + dead) assemblages
- Live foraminifera account for 1 - 22 % of total populations
- Two dominant species in live populations:
  - *Haynesina germanica* \*
  - *Elphidium williamsoni* \*

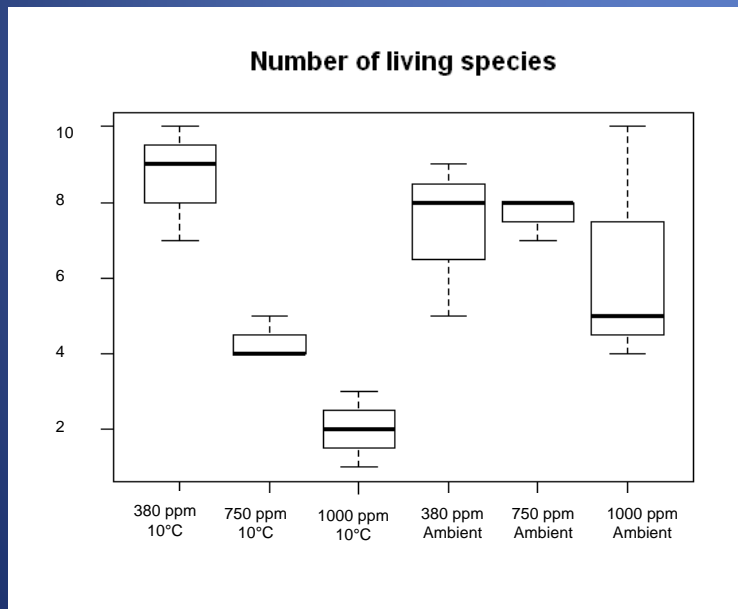

## Preliminary Observations (2):

- Highest number of living species present at 380 ppm
- Fewer live individuals in highest CO<sub>2</sub> treatments
- More agglutinated individuals in highest CO<sub>2</sub> treatments

Initial plots for week 36:

( $df_1 = 2$ ,  $df_{12} = 12$ ,  $F = 4.411$ ,  $p = 0.037$ )

## Preliminary Observations (3): Deformation and dissolution

Several different modes of abnormality in test morphology observed:

- Abnormal chamber additions
- Aberrant chamber shape
- Distorted chamber arrangement
- Reduced chamber size
- Reduction in ornamentation

380 ppm

1000 ppm

380 ppm

1000 ppm

## 8. Future Work:

**To provide valuable insight into foraminiferal response to ocean acidification:**

- Keep picking forams! (Complete time-series)
- Establish a dissolution index
- Identify species specific sensitivities to changing  $p\text{CO}_2$  & temperature
- Document changes in dominance and species diversity
- Quantify growth effects e.g. Maximum test diameter, test thickness

Thank you for your attention
